Acknowledgements

I would like to acknowledge the considerable contribution made to this publication by the following members of the Epidemiology Unit: Bruce Shadbolt, Carol Gilbert and Ursula White. In addition, I would like to thank the members of the ACT Cancer Registry Advisory Committee, and Marylon Coates and Noreen Panos from the NSW Cancer Council for their continued support and assistance.

The majority of the death data contained in this publication has been obtained from the ACT Registrar of Births, Deaths and Marriages, and the incidence data has been provided by medical records, clinicians, pathology laboratories, and medical practitioners. I would like to thank all those who have contributed to the publication.

Foreword

I am pleased to present this second report on cancer incidence and mortality in the Australian Capital Territory from 1983 to 1992. The report was produced by the ACT Cancer Registry which is located in the Epidemiology Unit, Population Health Division of the Department of Health and Community Care.

As for the rest of Australia, cancer is a leading cause of death in the Australian Capital Territory, and is the major cause of premature mortality. It is estimated that one in four persons will develop a cancer at some period in their lives, and although not all cancers are fatal, one in eight persons will die from cancer. The Department recognises the impact of cancer as a disease in the community and has recently commissioned a number of innovative programs to assist in the control and prevention of this major cause of morbidity and mortality. These measures include a Cancer Services Strategic Plan, a hospital-based cancer registry and a palliative care project.

The data for this report was collected by the NSW Central Cancer Registry and analysed here in the ACT. In July 1994 legislation was passed in the ACT making it mandatory to notify new cases of cancer. One of the major benefits from this legislation is that information about the incidence of cancer will be far more complete, which in turn will assist policy development and service delivery. This report is an important link in the effective treatment and control of cancer in the ACT.

Doris Zonta
General Manager

Introduction

This report documents incidence and mortality from cancer during the period 1983 to 1992 in the Australian Capital Territory. It is the second report produced by the ACT Department of Health and Community Care since 1994 when reporting of the incidence of cancer became mandatory. Monitoring the incidence of cancer is an important public health function as approximately one in four ACT residents will develop a cancer at some time in their life. In addition, in 1992 cancer was the second leading cause of death for both males and females, and as the population ages we can expect the incidence of cancer to increase.

The data for this report come from the New South Wales Central Cancer Registry which has been collecting data on cancer in the ACT since 1972. One of the major reasons why NSW has maintained ACT incidence data is because of the considerable cross-border use of medical services between the ACT and NSW. Although cancer notification was not compulsory in the ACT during the time covered by this report, the major hospitals and pathology laboratories in the ACT reported new cancer cases to the NSW Central Cancer Registry. However, not all cases of cancer in the ACT will have been registered by the NSW Registry, and all rates and numbers in this report are likely to be under-estimates to some degree. In particular, cases of breast and prostate cancer treated at John James Private Hospital are likely to be major exclusions. Although the extent of the under-enumeration is probably not great, caution should nevertheless be used when interpreting results in this report. In general five year averages were examined throughout the report because of the fluctuations and reliability of estimates that result from small numbers.

The structure of the report is as follows:

- trends using age-standardised rates for incidence and mortality over the period 1983 to 1992;
- age-specific new cases and deaths from cancer tables for males, females and persons for the two five year periods 1983-1987 and 1988-1992;
- most common new cases and deaths from cancer tables for males, females and persons for the two five year periods 1983-1987 and 1988-1992;
- site-specific tables for male, females and persons. These tables contain the number of cases, crude rate, lifetime risk of cancer, age-standardised rate and associated confidence interval, and the percentage of cancer cases that the particular cancer accounts for.
- information for the most common sites is expanded to include age-specific graphs, a short commentary, and age-standardised comparisons with NSW and Australia.

Time trends in cancer incidence and mortality 1983-1992 (ICD-9 codes 140 to 208)

Figure 1: Incidence of cancer

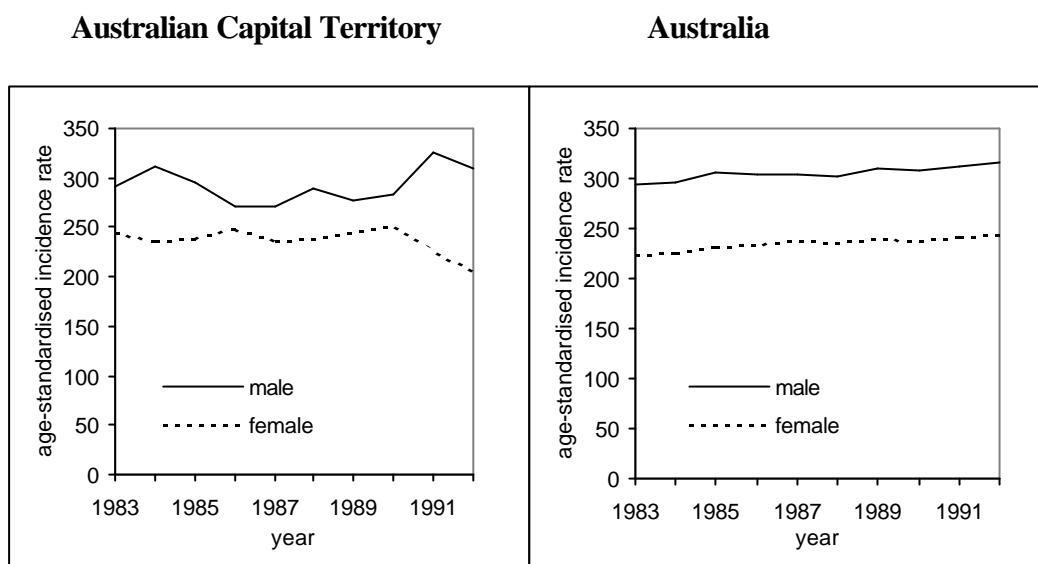

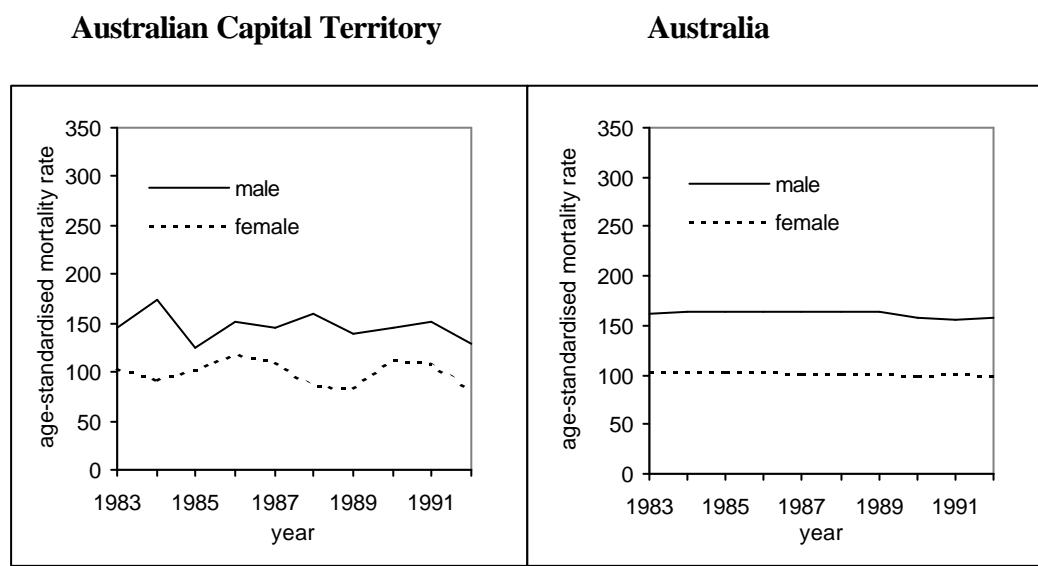

Figure 2: Cancer mortality

Time trends in cancer incidence and mortality 1983-1992

In 1983 the population of the ACT was estimated to be 238,983, of these 119,442 were males and 119,541 were females. The population grew throughout the 1980s and early 1990s from a combination of natural increase and immigration, and by 1992 there were an estimated 147,404 males and 146,755 females, a total of 294,159 persons. The ACT differs demographically from the rest of Australia in two respects, first it has a comparatively young age structure, due mainly to high immigration of younger persons in the 1970s and 1980s. Second it has a relatively homogenous population with a higher socio-economic status than other major cities.

During the ten year period from 1983 to 1992 6,060 people in the ACT were diagnosed with cancer, of these 3,061 were males and 2,999 were females. During the same time 1,412 males and 1,233 females died from cancer. The crude incidence rate for males rose from 208 to 263 per 100,000 males, mainly due to an increase in notifications of cancer of the prostate, and a greater effort by the NSW Cancer Registry in the early 1990s to collect notifications. For the same period the crude incidence rate for females, and the crude mortality rate for males and females remained relatively constant.

A crude rate is influenced by the age structure of the population, and to overcome this problem and present a more accurate perspective over time age-standardised rates have been calculated (see Figures 1 and 2). In 1983 the age-standardised incidence rate (per 100,000) in the ACT for males was 292. This rate fluctuated throughout the 1980s, and the trend showed no clear signs of an increase or decrease (see Figure 1). On the other hand, the female age-standardised rate remained similar to the 1983 rate of 244 for most of the period. Throughout the period the age-standardised incidence rate was lower for females than for males. Since about 1990 there has been a downward trend for females. This decrease may be due to the lack of completeness of data from private hospitals rather than the effects of a real decrease.

The age-standardised mortality trend for males follows much the same pattern as the age-standardised incidence rate, although the rates are substantially lower (see Figure 2). The mortality rate for males in 1983 was 146 deaths per 100,000 males, and ten years later in 1992 the rate was slightly lower at 128 deaths. The female age-standardised mortality rate revealed quite pronounced rhythmic peaks and troughs throughout the time series. For example, in 1989 the rate was 83 per 100,000 females, and in 1990 the rate was 112 per 100,000. This fluctuation was mainly due to the comparatively small numbers.

The fluctuations in the incidence and mortality of cancer in the ACT are particularly pronounced when compared to Australian rates (see Figures 1 and 2). These fluctuations mean that in a particular year, the ACT may have a higher or lower rate than the national average. For example, in 1990 the age-standardised mortality rate for females was 112 compared to 100 for Australia; while in 1989 it was 83 in the ACT and 102 nationally. Such variations make it difficult to assess the relative level of cancer in the ACT during a single year. Consequently, five year averages have been used throughout publication.

Most common cancers

Males

There were substantial changes in the order of the most common sites of newly diagnosed cancer for males between 1983-87 and 1988-1992 (see Tables 3 and 4). In particular, cancer of the prostate rose from the fourth most commonly diagnosed site in 1983-1987 to the most common site in 1988-1992. The number of cases increased from 181 to 254. The best explanation for this increase is improved diagnosis, stemming from the rise in the use of prostate specific antigen tests, and the more recent use of transrectal ultrasonography rather than a change in risk. Other changes include the fall of cancer of the colon from the third most common cancer in 1983-1987, to the fourth in 1988-1992, although the age-standardised rate increased marginally from 28 to 30 per 100,000 males. On the other hand, cancer of the kidney rose from 12th to 7th place.

In relation to mortality (see Tables 5 and 6) cancer of the lung remained by far the most common cause of cancer death in both periods. While the number of cases increased from 141 to 179, the age-standardised rate declined from 34 to 33 per 100,000 males. Cancer of the prostate remained the second most common cancer cause of death, and the mortality age-standardised rate increased from 13 to 16 per 100,000 males between 1983-87 and 1988-1992.

Females

Over the two periods the order of sites for newly diagnosed cancers for women remained relatively constant (see Tables 3 and 4) with minor variations. By far the most common site was the breast, followed by melanoma and the colon. Cancer of the breast, however, showed a substantial rise in the age-standardised rate between the periods. Like cancer of the prostate, this increase probably reflects changes in screening practices rather than risk.

In contrast the mortality pattern for women changed considerable over the two periods (see Tables 5 and 6). Breast cancer remained the leading cause of death for women between the two periods. Although the number of deaths increased from 122 to 140, the mortality crude and age-standardised rate remained much the same. Cancer of the lung moved from third most common cancer death in 1983-1987 to second in 1988-1992. This rise was also reflected in a significant increase in the age-standardised mortality rate from 11 to 13 per 100,000 females. Cancer of the colon declined from second to third most common cause of cancer death for females, and the age-standardised rate followed this trend. Both the number of deaths and the mortality age-standardised rate declined for cancer of the ovary, from 40 to 35 and 8 to 5 respectively.

Cancer of the stomach (ICD-9 code 151)

Figure 3: Age-specific incidence

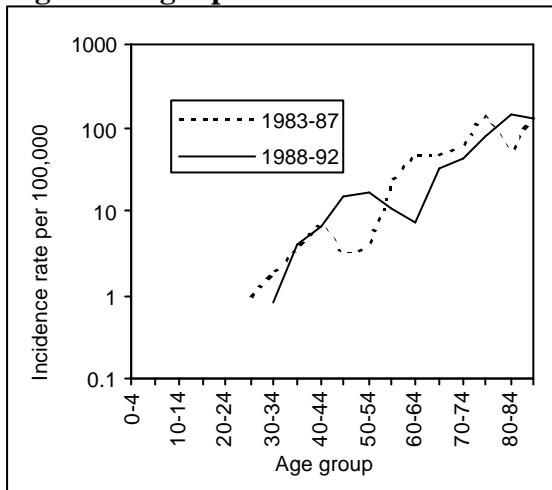

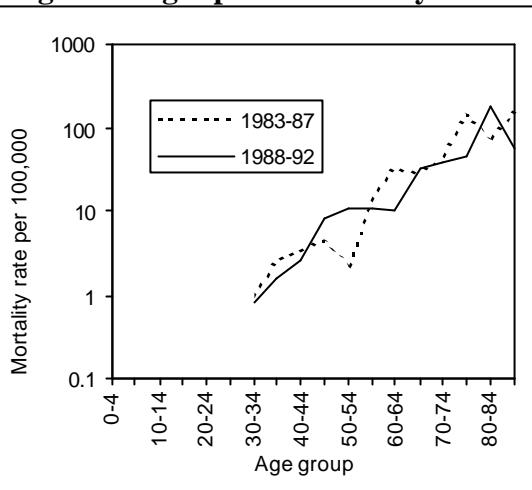

Figure 4: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- 98 new cases of stomach cancer were reported during the period from 1988 to 1992. It was the 11th most common site for males and females. There was a small decline in the crude incidence rate from 7.2 to 6.9 per 100,000 persons between 1983-87 and 1988-1992. The age-specific incidence rates for 1988-1992 followed a similar overall pattern to 1983-87 rates - the difference may be due in part to the effect of the small number of cases. The sex ratio of new cases of stomach cancer remained high at 145 males per 100 females reported in 1988-1992.
- There were 74 deaths from stomach cancer in the period 1988-1992. For males it was the fourth, and for females the tenth most common cause of death in this period. The crude mortality rate improved marginally from 5.6 to 5.2 per 100,000 persons between the two periods, and the age-specific rates for the two periods followed a similar pattern. The sex ratio increased from 163 to 196 males per 100 females between 1983-1987 and 1988-1992.
- The age-standardised incidence and mortality rate of stomach cancer for males and females declined between the two periods of study in the ACT. The male incidence rate in 1988-1992 was slightly lower than NSW or total Australia, while the female incidence rate was higher. The mortality rate was slightly higher for males in ACT, but much the same for females as NSW or total Australia.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	11.9 (8.7 - 15.1)	9.8 (7.2 - 12.4)	10.6 (9.5 - 11.7)	10.8 (10.2 - 11.4)
Females	6.5 (4.3 - 8.6)	5.3 (3.6 - 6.9)	4.0 (3.5 - 4.7)	4.2 (3.9 - 4.6)
Persons	7.2 (7.1 - 10.9)	7.3 (5.8 - 8.7)		7.2 (6.9 - 7.6)
Age-standardised mortality rates				
Males	9.9 (6.9 - 13.0)	8.6 (6.1 - 11.0)	7.8 (6.9 - 8.8)	7.1 (6.6 - 7.6)
Females	5.0 (3.1 - 6.9)	3.2 (1.9 - 4.5)	3.3 (2.8 - 3.9)	3.3 (3.0 - 3.6)
Persons	7.1 (5.4 - 8.8)	5.6 (4.3 - 6.9)		5.0 (4.7 - 5.2)

Note: Rates are expressed per 100,000 population and age-standardised to the world standard population

ACT Cancer Society

The ACT Cancer Society was founded in 1969 by Canberra people to serve the community of the Canberra region.

The society aims to reduce the incidence and impact of cancer in our community and to achieve this aim the society undertakes to provide a wide range of services.

For more information about the activities and services of the ACT Cancer Society, please phone (06) 285 3070 or call in to 15 Theodore Street, Curtin, ACT 2605

Cancer of the colon (ICD-9 code 153)

Figure 5: Age-specific incidence

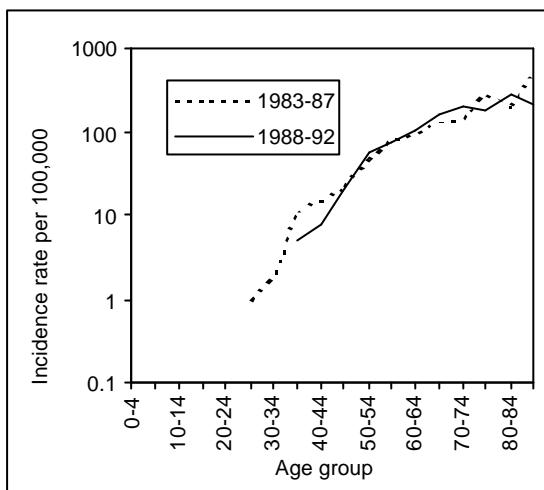

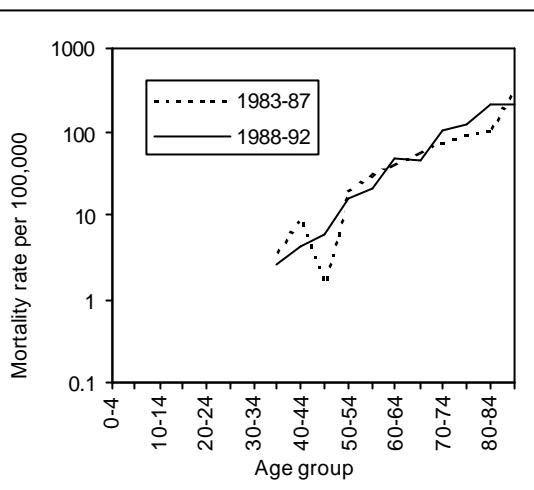

Figure 6: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- Cancer of the colon, like most cancers, is very much an age-related event - there were no cases reported in persons under the age of 25 years. It was the fourth most common site of new cancers for males (169 cases), and the third most common incidence site for females (141 new cases), during the five years to 1992. The crude rate increased from 20 to 22 new cases per 100,000 population between the periods 1983-1987 and 1988-1992 - the main contribution to this higher rate was the increase in the number of reported cases for males. The sex ratio for the new cases of cancer of the colon during the period 1983-1987 was 103 males to 100 females compared to 120 males to 100 females in 1988-1992.
- During the period 1988-1992 cancer of the colon was the third leading cause of death in the ACT for both males and females (69 deaths each). The crude mortality rate increased from 8.5 to 9.8 per 100,000 population, and as a proportion of all deaths cancer of the colon increased from nine to ten per cent between the two periods.
- The age-standardised incidence rate for males was slightly higher than in NSW or Australia. In general the ACT age-standardised mortality rate was lower than the Australian rate for both males and females. This may reflect earlier diagnosis in the ACT, and therefore higher incidence but lower eventual mortality.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	27.8 (22.8 - 32.8)	29.5 (25.0 - 34.0)	27.1 (25.4 - 28.8)	27.1 (26.1 - 28.2)
Females	22.2 (18.2 - 26.2)	20.8 (17.3 - 24.3)	20.7 (19.3 - 22.2)	21.4 (20.5 - 22.3)
Persons	25.1 (21.9 - 28.2)	25.2 (22.4 - 28.1)		23.9 (23.3 - 24.6)

Cancer of the rectum (ICD-9 code 154)

Figure 7: Age-specific incidence

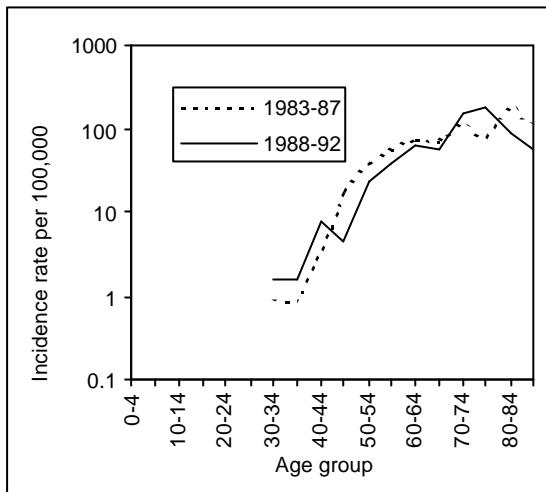

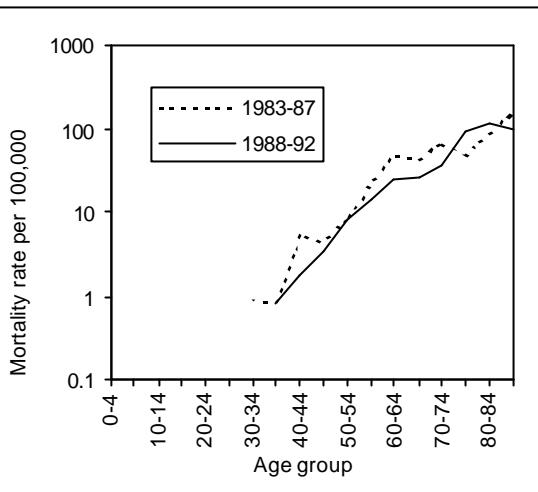

Figure 8: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- The incidence of cancer of the rectum was consistent during the two periods 1983-1987 and 1988-1992. For both males and females cancer of the rectum was the fifth leading cause of death in 1983-1987 and the sixth in 1988-1992. Although the actual number of cases increased from 150 to 170, the crude incidence rate was similar at 12 per 100,000 persons in both periods, this was due to the increasing population at risk. The sex ratio was 130 males per 100 females in the latter period.
- There were 73 deaths from cancer of the rectum in the period 1988-1992, a decrease of eight over the previous period. The crude rate declined from 6.4 to 5.2 per 100,000 persons between 1983-1987 and 1988-1992. As a result this cancer fell from third to sixth ranking for males, and from sixth to seventh for females.
- The ACT age-standardised incidence rates are similar to the Australian rate. But the age-standardised mortality rates are higher for both males and females, and more like those of NSW than the Australian rate.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	19.6 (15.3 - 24.0)	17.0 (13.5 - 20.5)	18.9 (17.5 - 20.4)	17.6 (16.8 - 18.4)
Females	11.6 (8.7 - 14.6)	11.0 (8.4 - 13.6)	9.2 (8.3 - 10.2)	10.0 (9.4 - 10.6)
Persons	15.2 (12.7 - 17.6)	13.7 (11.6 - 15.8)		13.5 (13.0 - 14.0)
Age-standardised mortality rates				
Males	12.7 (9.1 - 16.4)	8.1 (5.6 - 10.6)	8.6 (7.7 - 9.6)	6.1 (5.6 - 6.6)
Females	5.1 (3.2 - 7.0)	4.2 (2.6 - 5.7)	3.8 (3.3 - 4.5)	2.9 (2.6 - 3.2)
Persons	8.3 (6.5 - 10.2)	5.8 (4.5 - 7.2)		4.4 (4.1 - 4.6)

Note: Rates are expressed per 100,000 population and age-standardised to the World Standard Population

ACT Breast Screening Clinic

Early detection of breast cancer increases the chances of successful treatment and often allows more treatment options.

The ACT Breast Screening Clinic accepts women aged 40 and over for free breast screening mammography. A doctor's referral is not necessary.

For more information about the services of the ACT Breast Screening Clinic, please phone (06) 205 4444

Cancer of the trachea, bronchus and lung (ICD-9 code 162)

Figure 9: Age-specific incidence

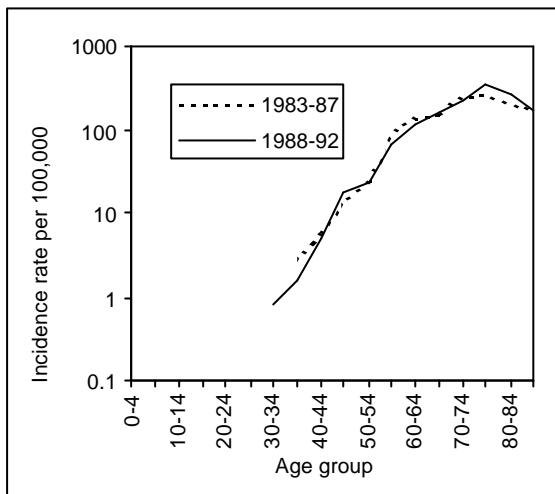

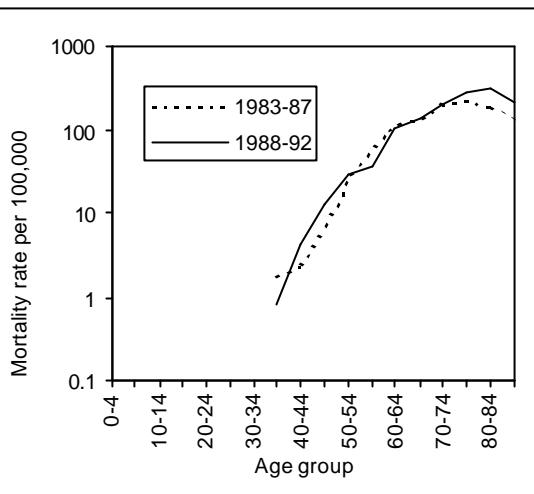

Figure 10: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- During both study periods cancer of the trachea, bronchus and lung was the second most common incidence site for males (177 and 214 cases respectively), and the fourth most common incidence site for females (75 and 93 cases). The crude rate increased for both males (28 to 30 per 100,000 males) and females (12 to 13 per 100,000 females) during the ten year period. The sex ratio declined marginally from 236 to 230 males per 100 females, but still reflects the huge disparity between the sexes which is mainly thought to be due to cigarette smoking (Mathers:1994;193)
- Cancer of the trachea, bronchus and lung was the leading cause of cancer deaths for males in both 1983-1987 (141 deaths) and 1988-1992 (179 deaths). At the same time the number of female deaths from this cancer site increased from 57 to 87, and this was reflected in the rise from third to second most common cause of cancer. The crude mortality rate increased for both males (from 22 to 25 per 100,000 males) and females (from 9 to 12 per 100,000 females). The sex ratio decreased from 189 to 152 males per 100 females, due mainly to the decline in male mortality.
- The age-standardised incidence and mortality rate for males in the ACT are lower than NSW and total Australia, possibly reflecting lower smoking rates in the ACT than the rest of Australia. ACT females have a lower age-standardised incidence rate, but have similar age-standardised mortality rates to the rest of Australia.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	41.7 (35.3 - 48.0)	39.3 (33.9 - 44.7)	46.6 (44.4 - 48.9)	45.8 (44.5 - 47.1)
Females	14.2 (10.9 - 17.4)	13.8 (10.9 - 16.7)	14.6 (13.4 - 15.8)	15.2 (14.5 - 15.9)

Cancer of the skin - melanoma (ICD-9 code 172)

Figure 11: Age-specific incidence

Figure 12: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- One of the most notable features of melanoma of the skin is the relatively high incidence compared to deaths from this cancer, in the period 1988-1992 the respective crude rates were 27 and 4 per 100,000 persons. Melanoma of the skin also differs in that its prevalence is comparatively high in the younger age groups. In the period 1988-1992 there were eight reported cases in the 15-19 years age group. For males and females in both study periods the incidence of melanoma was among the top three most common cancers. The sex ratio in this period was 115 males to 100 females.
- There were 55 deaths in the period 1988-1992 compared to 38 deaths in 1983-1987, and during this period the rate increased from 3 to 4 per 100,000 persons. The mortality sex ratio, 190 males per 100 females, was substantially higher than the incidence sex ratio. This may reflect the fact that men often delay treatment of melanoma of the skin until the condition is life threatening (Jelfs:1994).
- The age-standardised incidence rate of melanoma was remarkably consistent for the ACT, NSW and Australia. There was more variation in the age-standardised mortality rates but this could be due, in part, to fluctuating small numbers in the ACT.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	30.1 (25.5 - 34.7)	30.6 (26.2 - 34.9)	31.2 (29.4 - 33.2)	30.9 (29.8 - 32.0)

Cancer of the female breast (ICD-9 code 174)

Figure 13: Age-specific incidence

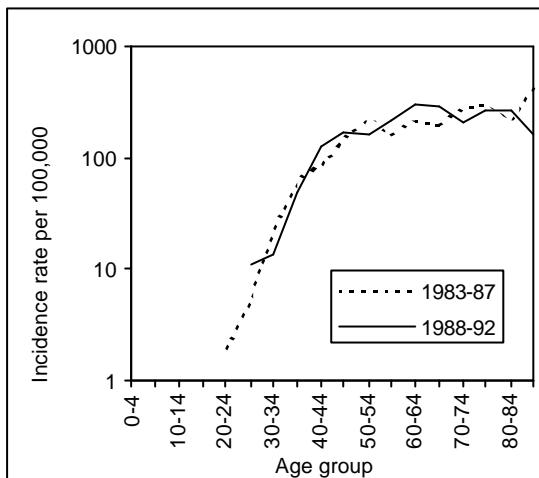

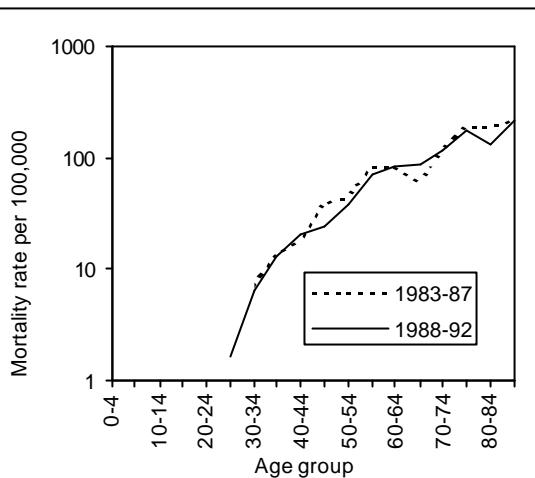

Figure 14: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- The incidence of cancer of the female breast was higher in the period 1988-92 compared to the period 1983-87 (478 cases and 358 cases respectively). Characteristics common to both periods was the early onset and relatively high incidence in the middle age groups, and the plateauing out in the older age groups. There is evidence that the increase in diagnosed cases, particularly in the 50-69 year olds, may be due to the early detection of cancers by mammography. In 1994 stage one breast cancers had a five-year survival of about 90 percent, and the overall five-year survival was 70 per cent (South Australian Health Commission:1994). The crude incidence rate rose from 57 to 68 per 100,000 females during the study period, and the lifetime risk increased from 1 in 15 to 1 in 13.
- 123 women died from breast cancer in the period 1983-1987, and 142 died in the period 1988-1992. However, unlike the crude incidence rate the crude mortality rate was similar for both periods at 20 per 100,000 females, indicating that the additional deaths were mainly due to the gradual ageing and growth of the female population rather than an increase in the disease. The lifetime risk that a woman may die from breast cancer was 1 in 44 in 1988-1992.
- The ACT has a higher age-standardised incidence rate of breast cancer, but has very similar age-standardised mortality rates to the rest of Australia.

Cancer of the cervix uteri (ICD-9 code 180)

Figure 15: Age-specific incidence

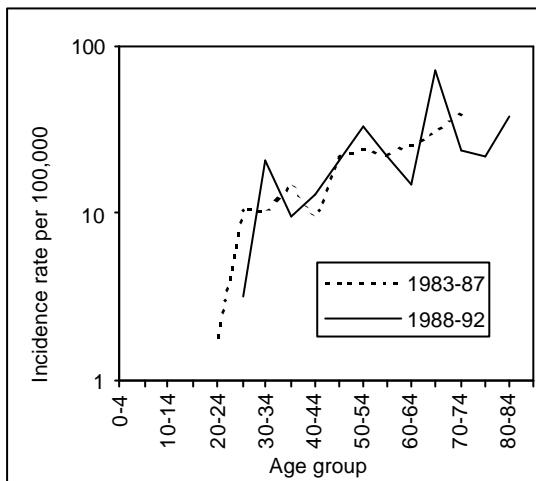

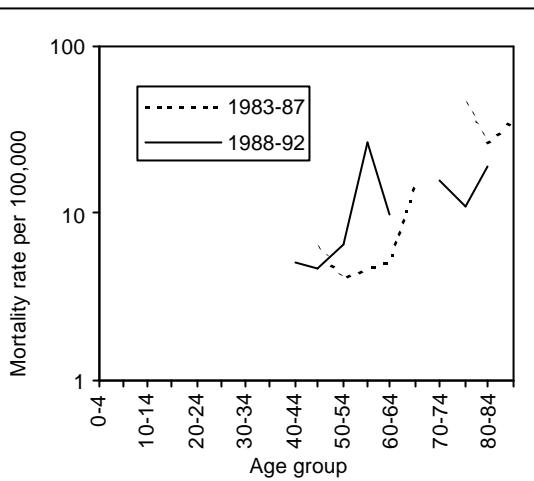

Figure 16: Age-specific mortality(a)

Note: a log scale has been used to clarify presentation in the younger age groups.

(a) No deaths occurred in the 70-74 years age group in 1983-1987, and 65-69 years age group in 1988-1992.

- Cancer of the cervix uteri was the fifth most common incidence of cancer in 1988-1992. The incidence of this cancer rose from 58 cases in 1983-1987 to 76 cases in 1988-1992, representing an increase in the rate from 9 to 11 per 100,000 females. The increase may be the result of greater participation in screening leading to earlier detection - it is estimated that 90 per cent of cases of cervical cancer are preventable with biennial screening (Jelfs:1995;1). As with most cancers, the risk of cancer of the cervix increases significantly with age, but recent studies also indicate rising incidence in younger women (Jelfs:1995;6). Between the two study periods the lifetime risk of the incidence increased from 1 in 95 to 1 in 86.
- Mortality from cancer of the cervix is relatively low compared with its incidence. 14 women died in the period 1983-1987 and 19 from 1988-1992. The rates were similar (2 and 3 per 100,000 females respectively) over the ten year period, but the risk rose from a lifetime risk of 1 in 516 to 1 in 294. This was due in part to an increase in deaths in the relatively younger age group 55-59 years (six deaths in 1988-1992).
- The age-standardised incidence and mortality rates for the ACT were very similar to those of NSW and Australia.

Cancer of the ovary and other uterine adnexa (ICD-9 code 183)

Figure 17: Age-specific incidence

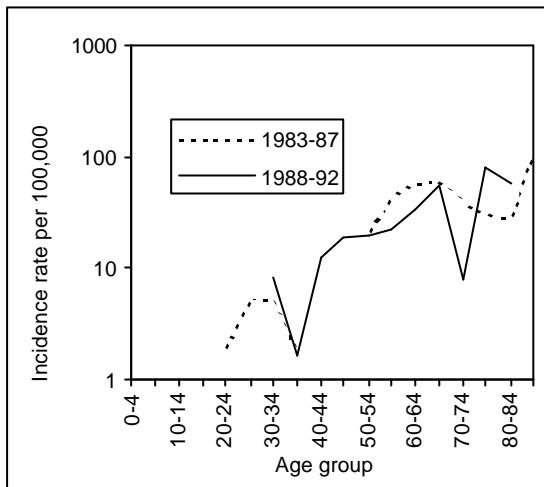

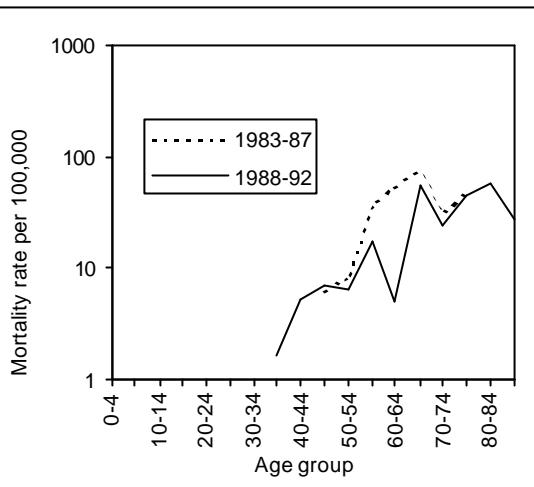

Figure 18: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- Cancer of the ovary and other uterine adnexa was the eighth most common cancer in both 1983-1987 (52 cases) and 1988-1992 (61 cases). The crude incidence rate was similar in both periods, and the lifetime risk decreased marginally from 1 in 86 to 1 in 111.
- In contrast to cancer of the cervix uteri the relationship between the incidence and mortality of this cancer was much closer, the lifetime incidence risk being one in 111 and the lifetime mortality risk one in 165. Cancer of the ovary and other uterine adnexa was the fifth most common cause of cancer death in 1988-1992, and the crude rate decreased during the ten year period from 7 to 5 per 100,000 females. The lifetime risk decreased substantially between the two periods from one in 96 to one in 165.
- The age-standardised incidence rate for ACT was similar to NSW and Australia, but the age-standardised mortality rate was significantly lower than Australia.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates

The Pap Smear Register

The register is a central and confidential list of ACT women's Pap smear results. Pap smears are recommended every two years for women aged between 18 years and 70 years who have ever been sexually active. The Pap smear register does not offer a service for taking Pap smears, it simply records the results and sends reminders for overdue Pap smears.

Inclusion on the register is on a voluntary basis.

For more information about the

Pap Smear Register

please phone (06) 205 1545

Cancer of the prostate (ICD-9 code 185)

Figure 19: Age-specific incidence

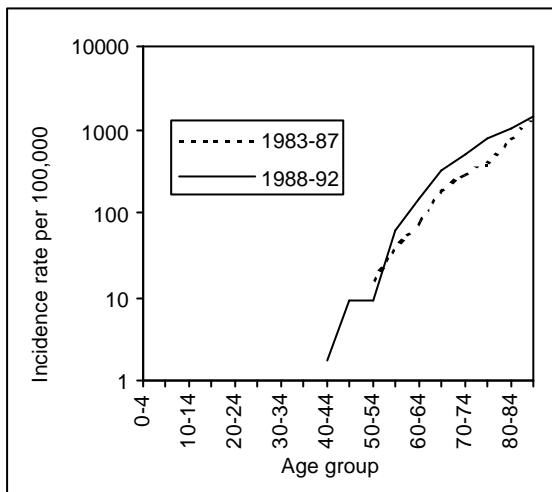

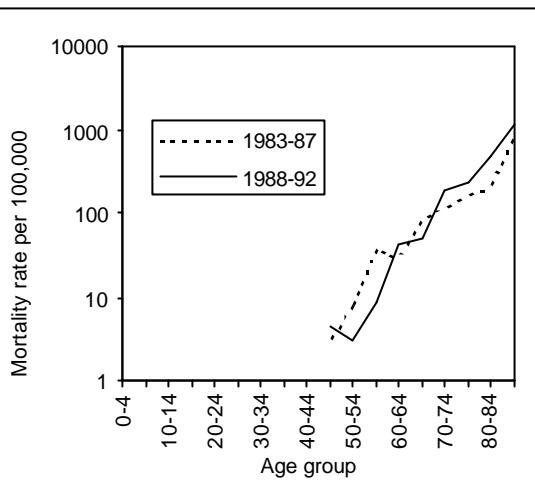

Figure 20: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger groups.

- Cancer of the prostate rose from fourth to the most common cancer in men between 1983-1987 and 1988-1992. This increase is due in part to increased use of screening tests which has resulted in earlier diagnosis of clinically silent cancers. This hypothesis is supported by the fact that more cases were detected in younger age groups in the latter period. Although there is evidence that earlier diagnosis has resulted in increased five year case-survival rates (from 57% to 68% over the period 1977-1992), it has also been suggested that increased investigation has disclosed cancers that may otherwise have been diagnosed as benign hyperplasia (SA Health Commission:1994;22). The crude rate increased from 18 to 36 per 100,000 males, and at the same time the lifetime risk rose from 1 in 33 to 1 in 19.
- In both periods cancer of the prostate was the second most common cause of cancer death in men (54 deaths in 1983-1987 and 85 in 1988-1992). The rate increased from 9 to 12 per 100,000 males, and at the same time the lifetime risk rose from 1 in 73 to 1 in 68. Contributing to these higher indicators was the ageing ACT population, and subsequently a greater proportion of males moving into the high risk age groups for this particular cancer.
- Between the two study periods the age-standardised mortality rate increased significantly in the ACT. The age-standardised incidence and mortality rates for the period 1988-1992 were similar in the ACT to NSW and Australia.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	31.3 (25.2 - 37.4)	50.0 (43.6 - 56.3)	50.6 (48.4 - 52.9)	50.4 (49.0 - 51.7)
Age-standardised mortality rates				
Males	15.1 (10.7 - 19.4)	18.2 (14.1 - 22.2)	19.9 (18.5 - 21.3)	17.8 (17.0 - 18.6)

All lymphoma cancers (ICD-9 codes 200-202)

Figure 21: Age-specific incidence

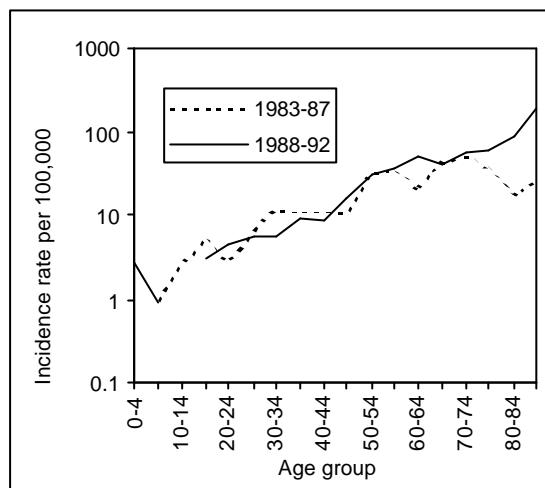

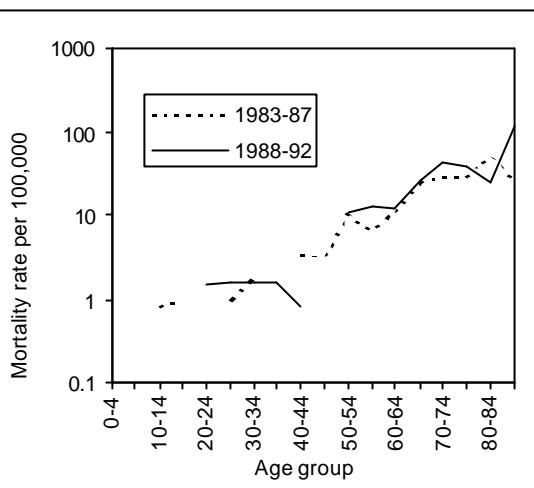

Figure 22: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- Non-Hodgkin's lymphomas account for nearly 90 per cent of all new cases of lymphoma. In Victoria during the period 1980-1989 lymphoma accounted for 13 per cent of all childhood cancers (Cancer Epidemiology Centre:1994), and there is no reason to expect the ACT to be different, although a detailed analysis is not possible at this time. Overall, lymphomas of all kinds were the fifth most common cause of cancer for males and the seventh for females in the ACT during the period 1988-1992. The incidence of this group of cancers increased from 10 to 12 per 100,000 population between 1983-1987 and 1988-1992. This increase is mainly due to higher rates in males aged between 45 and 54 years of age, and in the oldest age group.
- The number of cases in the younger age groups is too small in the ACT to establish if there has been any overall improvement in survival rates, as indicated by evidence from South Australia and Victoria (SAHC:1994, Cancer Epidemiology Centre:1994). In the ACT the overall mortality rate increased from 3 to 4 per 100,000 persons, mainly due to an increase in deaths in the middle age groups. The lifetime risk for males increased from 1 in 240 to 1 in 152 over the study period.
- The age-standardised incidence rate was significantly higher in the ACT than NSW or Australia, but the age-standardised mortality rate was similar. Again reflecting a common pattern in the ACT of higher incidence and lower mortality than NSW or Australia.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	13.1 (9.9 - 16.3)	15.9 (12.6 - 19.1)	14.8 (13.5 - 16.2)	14.0 (13.2 - 14.7)
Females	9.3 (6.8 - 11.8)	10.7 (8.2 - 13.3)	8.7 (7.7 - 9.7)	9.9 (9.3 - 10.5)
Persons	10.9 (9.0 - 12.9)	13.2 (11.2 - 15.3)		11.8 (11.3 - 12.3)
Age-standardised mortality rates				
Males	4.1 (2.1 - 6.2)	5.5 (3.5 - 7.4)	6.6 (5.8 - 7.5)	6.7 (6.2 - 7.2)
Females	3.9 (2.2 - 5.5)	4.3 (2.7 - 5.9)	4.4 (3.8 - 5.1)	4.1 (3.7 - 4.5)
Persons	3.9 (2.7 - 5.1)	4.9 (3.7 - 6.2)		5.3 (5.0 - 5.6)

Note: Rates are expressed per 100,000 population and age-standardised to the world standard population.

All leukaemias (ICD-9 codes 204-208)

Figure 23: Age-specific incidence

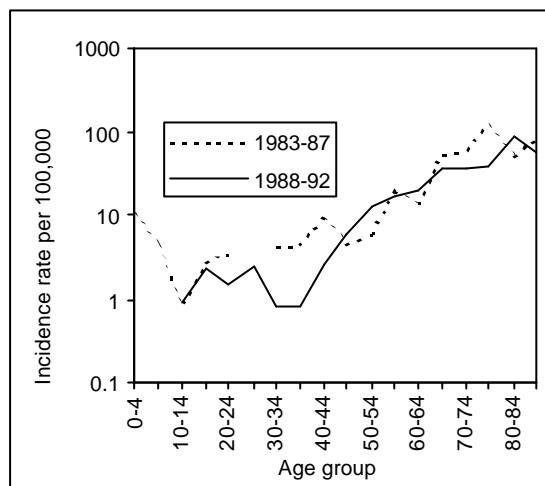

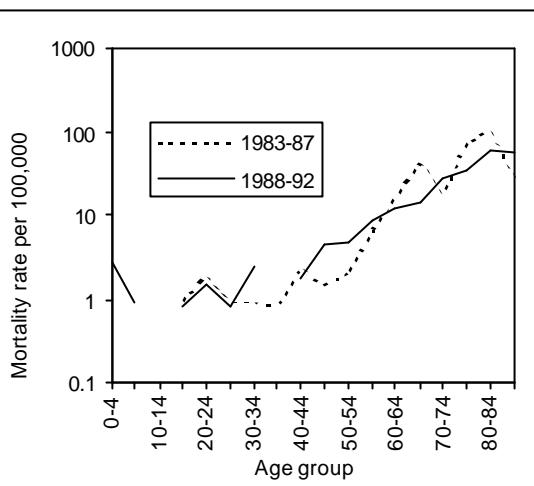

Figure 24: Age-specific mortality

Note: a log scale has been used to clarify presentation in the younger age groups.

- In Victoria leukaemia was the most common childhood cancer, and accounted for nearly 40 per cent of all cancers in the 0-4 years old age group (Cancer Epidemiology Centre:1994). For both males and females the incidence of all leukaemias declined between 1983-1987 and 1988-1992 (from a rate of 10 to 8 per 100,000 for males, and 6 to 4 per 100,000 for females). At the same time the lifetime risk declined from 1 in 104 to 1 in 137, and as a percentage of all cancers all leukaemias fell from four to three per cent.
- The crude mortality rate remained unchanged between the two study periods, however, there was considerable fluctuation in the sex ratio - in the period 1983-1987 92 males died for every 100 females, in the period 1988-1992 194 males died for every 100 females. This resulted in the crude mortality rate for males increasing from 3.7 to 5 per 100,000 males, while at the same time the rate for females decreased from 4 to 2.6 per 100,000 females. The increase in male deaths was distributed throughout the age range. The lifetime risk decreased from 1 in 217 to 1 in 244.
- The age-standardised incidence and mortality rates for all leukaemias were similar to the NSW population. Rates for all leukaemias are not available for Australia.

	ACT 1983-1987	ACT 1988-1992	NSW 1990	Australia 1990
Age-standardised incidence rates				
Males	13.8 (10.2 - 17.4)	10.5 (7.7 - 13.2)	9.1 (8.1 - 10.3)	Rates for all
Females	6.8 (4.6 - 9.0)	4.7 (3.0 - 6.4)	5.4 (4.6 - 6.2)	leukaemias not
Persons	9.9 (7.9 - 11.8)	7.4 (5.8 - 8.9)		published
Age-standardised mortality rates				
Males	5.3 (3.0 - 7.6)	6.1 (4.0 - 8.1)	6.1 (5.3 - 7.0)	
Females	4.3 (2.6 - 6.0)	2.4 (1.3 - 3.5)	3.4 (2.8 - 4.0)	
Persons	4.7 (3.3 - 6.1)	4.2 (3.0 - 5.3)		

Note: Rates are expressed per 100,000 population and age-standardised to the World Standard Population

Indices of data quality

There are several indices which are commonly used to assess data quality and reliability of cancer registration.

- Histological verification (%HV) is the percent of cases which have been confirmed by pathological study of tissue or blood. The higher the proportion of histological verification of diagnosis, the more certain it is that the neoplasms reported to the registry actually existed and were correctly diagnosed. This statistic can also be too high, suggesting that clinical diagnoses are not all being registered.
- Death certificate only (%DCO) is the percent of cancers which have not been notified to the registry except by a death certificate. If the proportion of cases registered only by death certification is high then it is probable that there is poor notification from other sources. This implies that non-fatal cases are being missed and that the recorded incidence rates are too low.
- Mortality/incidence ratio (%M/I) is the number of deaths from a cancer in one year divided by the number of new cases of that cancer in the same year (converted to a percentage). If the number of deaths exceeds the number of incident cases of cancer then registration of incident cases may be incomplete. In addition, cancers with high average survival rates should have low M/Is and cancers with low survival rates should have high M/Is.

Glossary

<i>Age-specific death rate</i>	The number of deaths per 100,000 population for age groups other than under 1 year.
<i>Age-specific incidence rate</i>	The number of new cases per 100,000 population for all age groups.
<i>Cancer(malignant neoplasm)</i>	a term used to describe one of several diseases which result when the process of cell division, by which tissues normally grow and renew themselves, becomes uncontrolled and leads to the development of malignant cells.
<i>Cancer incidence</i>	The number of new cancer cases.
<i>Confidence interval</i>	The age-standardised rate plus or minus 1.96 multiplied by the standard error of the rate.
<i>Crude rate</i>	Number of events occurring during the year per 100,000 of the estimated mean resident population at risk.
<i>Lifetime risk</i>	The measure which approximates the risk of contracting a particular cancer in a lifetime if the risks at the time of estimation remained throughout life.
<i>Cancer mortality</i>	A death where the primary cause if indicated as cancer. Persons with cancer dying of other causes are not counted in the death statistics in this publication.
<i>Per cent of all cancers</i>	The proportion than an individual cancer type accounts for among all cancers.
<i>Prevalence</i>	The number or proportion of the population suffering from a disease at a given point in time or over a given period.
<i>Sex ratio</i>	The number of males per 100 females.
<i>Standardised death rate</i>	The overall death rate that would have prevailed in a standard population if it had experience at each age the death rates of the population being studied. The standard population used in this publication is the World Standard Population.
